

Sales & Marketing Call Center Dashboard

Portfolio-ready analysis report | Interactive operational dashboard case study

BUSINESS INTELLIGENCE • CUSTOMER OPERATIONS

200,000 TOTAL CALLS	83,519 SUCCESSFUL	71,837 FAILED	44,644 ABANDONED
41.8% SUCCESS RATE	35.9% FAILURE RATE	22.3% ABANDONMENT RATE	69.0% TOP 5 AGENT SHARE

Figure 1. Call-center dashboard overview with agent, time, outcome, abandonment-reason, product, trend, and state filters.

Business question

Which operational factors are affecting call-center performance and customer experience, and where should management focus improvement efforts?

Project outcome

An interactive dashboard that combines call outcomes, agent workload, ratings, duration, abandonment reasons, product discussions, monthly trends, call-time filters, and customer geography.

Analysis and Key Findings

The dashboard summarizes 200,000 calls. Of these, 83,519 were successful, 71,837 failed, and 44,644 were abandoned. This means only 41.8% of all calls were successful, while 58.2% ended in failure or abandonment - the clearest operational issue in the dataset.

Area	Result	Business interpretation
Overall call outcome	41.8% successful; 35.9% failed; 22.3% abandoned	More than half of calls did not reach a successful outcome, creating a direct service and sales-performance improvement opportunity.
Workload concentration	Top five agents handled 69.0% of all calls	A relatively small group carried most call volume, which may create capacity, consistency, or coaching risks.
Agent call volumes	Ava Sandoval: 40,000; Elijah Hawkins: 32,000; Drew Clay: 28,000	The three highest-volume agents handled half of all calls, making their process quality especially important.
Displayed agent performance	Ava Sandoval: 20.0% success; Samuel Smith: 90.6% success	The dashboard displays a very large performance gap. This should prompt both coaching analysis and validation of the success-rate measure.
Customer gender mix	60,444 female calls; 139,556 male calls	Male customers represented 69.8% of calls, which may influence campaign targeting and product discussion patterns.
Geographic concentration	Top five states represented about 58% of calls in selected agent views	Call activity was concentrated geographically, supporting state-level staffing and campaign analysis.

Headline insight

The primary measurable issue is the non-success rate: failed and abandoned calls together represented 58.2% of all activity. Reducing either component would create a meaningful improvement in customer experience and potential sales conversion.

Agent-level evidence from the interactive view

Figure 2. Agent-level view for Samuel Smith, showing a displayed success rate of 90.6%, rating of 4.3, average duration of 16.9 minutes, and abandonment reasons.

Method, Contribution, and Recommendations

Workflow

- Used Power Query to clean and prepare the call-center data for analysis.
- Created DAX measures and PivotTable/PivotChart views for call outcomes, rates, agent metrics, ratings, durations, products, and geographic distribution.
- Designed interactive filters for agent, call time, and month so users could move from the overall operation to specific performance cases.
- Built the dashboard layout and connected the KPI cards, charts, maps, and slicers into one management view.
- Recorded a short interactive demonstration showing how the dashboard responds to filters.

My contribution

I prepared the dataset, selected and calculated the business indicators, created the analytical visuals, designed the dashboard, added the interactive controls, and interpreted the operational findings. The project demonstrates practical BI skills across data preparation, measure design, visualization, and business communication.

Business recommendations

- Treat the 58.2% combined failed-and-abandoned share as the first improvement target and track it by agent, time of day, month, and product.
- Investigate technical issues and long wait time at agent level, then separate system problems from staffing or process problems.
- Review why the top five agents handle 69% of calls and whether workload should be redistributed to reduce operational concentration.
- Compare the process used by high-performing agents with lower-performing agents, while first validating that the success-rate measure is calculated consistently.
- Use the time and geographic filters to align staffing and campaign activity with the periods and states generating the highest call demand.

Limitations and quality checks

The report uses the values visible in the dashboard recording. Before publishing a final case study, the success-rate definition should be checked against the underlying success/failure counts because some selected agent views appear to show large differences between the headline rate and product-level counts. Identifying and documenting that validation step would strengthen the project by demonstrating analytical quality control.

Portfolio summary

Built an interactive call-center dashboard for 200,000 calls. The analysis showed that 58.2% of calls failed or were abandoned, while the top five agents handled 69% of volume - clear evidence for prioritizing outcome improvement, workload review, and agent-level process analysis.
